## Introduction and background

As a result of the preliminary work done for another project (Aerial Surveillance Data for National Water Act Implementation), the Chief Director of Scientific Services requested additional summaries of the national land cover data in formats that the DWAF Resource Directed Measures office could use. The brief of this project was therefore to summarise data from the National Land Cover database in an electronic atlas for use in the Resource Directed Measures project.

The approach was to consolidate existing maps and develop new maps representing the drainage region hierarchy (primary, secondary, tertiary and quaternary) showing per catchment percentage of afforestation, irrigation and water bodies. A separate set of maps would summarise the desktop provisional reserve (Hughes and Münster, 1999) for flow. The maps should ideally be uncluttered, including only the most basic orientation information, e.g. Water Management Areas, catchments, rivers and dams.

The deliverables were thus an atlas in the form of web pages showing land cover statistics for drainage regions. The raw data scale is 1:250 000, so this is the best possible mapping scale for this project. Technical aspects of presentation meant that most products would be at a coarser scale than 1:250 000. During the course of the project, additional maps became necessary to provide more detail on wetland distribution and surface water quality. Ecological class maps developed earlier were placed on the site for convenience of access, and a set of locality maps was added for orientation.

The sequence of production was according to the priority catchment list and the proposed completion date for the web information was 29 September 2000.

## Methods

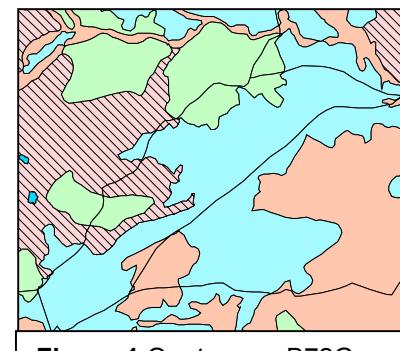

### ***Segmenting land cover by drainage region***

The Department of Water Affairs and Forestry was part of the consortium that funded the National Land Cover project, and therefore has a copy of the GIS coverage of land cover (Fairbanks *et al.*, 2000). An INTERSECT operation on the land cover coverage and quaternary drainage region coverage in Arc/Info

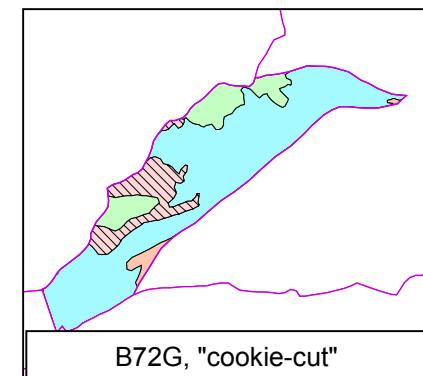

yielded a new coverage containing land cover information "cookie-cut" to drainage region borders. The data table associated with the combined coverage is easily converted to a comma-delimited format readable by other programs, not only ArcView but also other programs, such as spreadsheet packages. Note that scale differences between the two coverages can cause edgematch errors of 100 metres or more. One consequence is that many of the coastal quaternary drainage regions include slivers of marine water.

#### **INTERSECT process (takes several hours)**

```
Arc: intersect /hri2/waterm/wmdata/general/landcover
/hri/db/cover/s-africa/hca_4 lc_hca4 poly 1 join
Intersecting /hri2/waterm/wmdata/general/landcover with
/hri/db/cover/s-africa/hca_4 to create lc_hca4
Sorting...
Intersecting...
Assembling polygons...
Creating new labels...
Creating lc_hca4.PAT...
** Item "AREA" duplicated, Join File version dropped **
** Item "PERIMETER" duplicated, Join File version dropped **
** Item "AREA" duplicated, Join File version dropped **
** Item "PERIMETER" duplicated, Join File version dropped **
```

**Figure 1** Quaternary B72G,

B72G, "cookie-cut"

## Map production

### Water Management Areas

At the start of the project, the 1999 Water Management Area boundaries were used for map production, but during the project the 2000 boundaries became available. The 2000 boundaries were much the same as the earlier ones, with a few exceptions. The names for two of the WMAs changed ("Mzimvubu to Buffalo" became "Mzimvubu to Keiskamma" and "Fish to Gamtoos" became "Fish to Tsitsikamma". The boundaries between the Lower Orange, Middle Orange and Lower Vaal WMAs also changed slightly (catchment D33 is now in the Lower Orange). The new names and boundaries appear in some of the updated maps.

An adaptation of the Arc/Info Imagemap Macro (Thomas, 1998) automated the process of generating "clickable" maps for use on the Internet. The adaptation simplifies the process of generating images in Joint Photo Expert Group (JPEG or .jpg format) (Appendix ).

### Index of base flow

Prof. Dennis Hughes provided the estimated index of base flow (Hughes and Münster, 1999) to Adhishri Singh of the Resource Directed Measures office in spreadsheet form (2000-03-13). The estimates were tabulated by quaternary drainage region, allowing them to be linked to the quaternary drainage region coverage by means of the JOIN function in ArcView. The ArcView legend function shaded quaternary drainage regions using an arbitrary base flow index classification of 0 to 0.81 in steps of 0.09.

A script, WMA\_step.ave (Appendix ), automated the process of generating output. The script zooms into each water management area in turn and draws a standard map, then exports the map as a JPEG image for use in the Internet environment.

### Land cover

A series of maps showing the proportion of each cover type (normalised by area) highlight quaternary drainage regions dominated by forest, irrigation or water body land cover types. While this method produces striking maps on which drainage regions of interest stand out at a glance, it introduces bias into the results. A separate set of maps to illustrate this bias to the casual user, use simple HTML pages to allow the user to scan back and forth between different levels of data consolidation (HTML source in Appendix ).

A similar script to the base flow WMA\_step.ave utility generated sets of land cover maps for each Water Management Area.

### Surface water quality

A criteria table using "cut points" separates the water quality into four classes using the 95th percentile. Note that these classes are based on only a few water quality criteria, and that the algorithm classifies a whole quaternary drainage region on the basis of as few as 5 samples for a minimum of just one station. The algorithm classifies dams separately from the drainage region in which they occur. Such a gross summary means that the user must check the original data before drawing conclusions about individual catchments or dams. For example, coastal lakes may show up as poor quality because of their very high natural salinity.

Table of class definitions

Class	definition
0	ideal water
I	safe water
II	short-term use
III	undrinkable

Most variables have three cut points (and zero which, defines the minimum for Class 0), except pH, which needs six cut points to define acid and base ranges (with 7.0 as the central point).

Only one variable needs to be in a higher class for the algorithm to shift the whole classification to that class.

Units are mg/litre except pH (-log [H<sup>+</sup>]) and EC (millisiemens/m).

Table of concentration ranges used:

Variable	Units	Cut	Cut	Cut	Cut	Cut	Cut
		point 1	point 2	point 3	point 4	point 5	point 6
pH	-	4	5	6	9	9.5	10
Fluoride	mg/L	1	1.5	3.5			
Nitrate + nitrite	mg/L	6	10	20			
Sulphate	mg/L	200	400	600			
Chloride	mg/L	100	200	600			
Sodium	mg/L	100	200	400			

Variable	Units	Cut point 1	Cut point 2	Cut point 3	Cut point 4	Cut point 5	Cut point 6
Magnesium	mg/L	30	70	100			
Total dissolved salts	mg/L	450	1000	2450			
Electrical conductivity	mS/m	70	150	370			

The process of generating colour-coded maps of the chemical status of all South African quaternary drainage regions for which sufficient chemical data was available was automated using Arc/Info's macro language (AML). A listing of qtrivhtml.aml is available in Appendix .

## Ecological classes

Although not part of the brief of this project, several requests had come in for maps of ecological classifications (Kleynhans 1999). A manual ArcView procedure for generating ecological class maps was already available, and this was adapted to produce a set of maps on the web site under these headings:

Name	Description
DEMC	default ecological management class or category
PESC	present ecological status class or category
AEMC	(present) attainable ecological management class or category
AEMC	(best) attainable ecological management class or category
EISC	ecological importance and sensitivity class or category

## Orientation maps

A set of maps created in ArcView provided orientation information such as river, dam and town names for each water management area.

## Web page construction

Web pages were either generated automatically by the methods described above, or created manually with HTML-kit (Chami 2001) using the conventions for HTML 3.2 or 4.0.

The screenshot shows a web browser window with the following details:

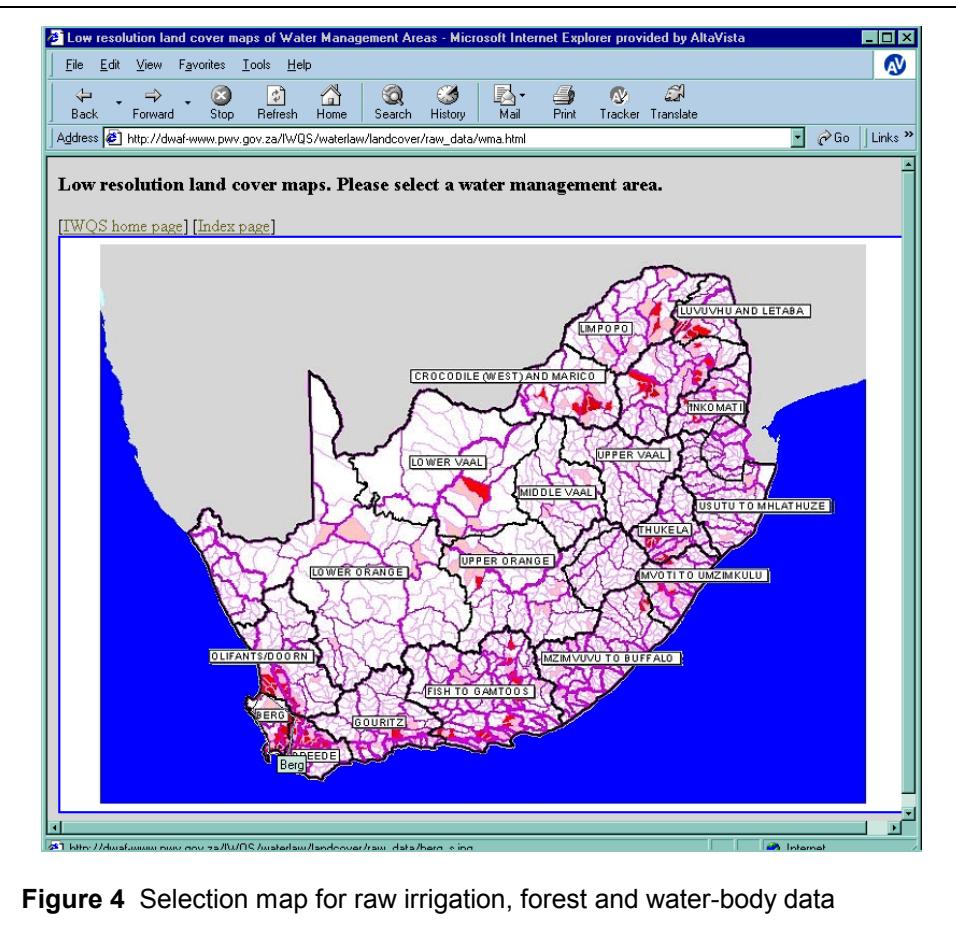

- Address bar:** http://dwaf-www.pwv.gov.za/IWQS/waterlaw/index.html
- Title bar:** WATER MANAGEMENT AREAS
- Left sidebar (blue background):**
  - Data mapped per quaternary drainage region.
  - Quaternaries grouped by Water Management Area
  - report N/0000/00/REQ/0700 (Draft)
  - National land cover atlas for the Resource Directed Measures programme
- Main content area (light green background):**
  - Maps of quaternary drainage characteristics, using available data: note that these maps are not definitive, but are provided as an aid to water resource management. Please note that the Water Management Area boundaries and names on many of the maps are as they appeared on the 1999 draft WMA map, and the 2000 final map names and boundaries differ slightly. The correct names for two of the WMAs are "Mzimvubu to Keiskamma" (not "to Buffalo") and "Fish to Tsitsikamma" (not "to Gamtoos"). The boundaries between the Lower Orange, Middle Orange and Lower Vaal WMAs have also changed slightly (catchment D33 is now in the Lower Orange). The new names and boundaries will appear in updated maps.
  - Contact [Adhishri Singh](#), Department of Water Affairs and Forestry, eManzini 437, Tel. (012) 336 8946 for more information about data sources.
  - Links to ecological classification maps:

Figure 2 Main intranet page

## Products

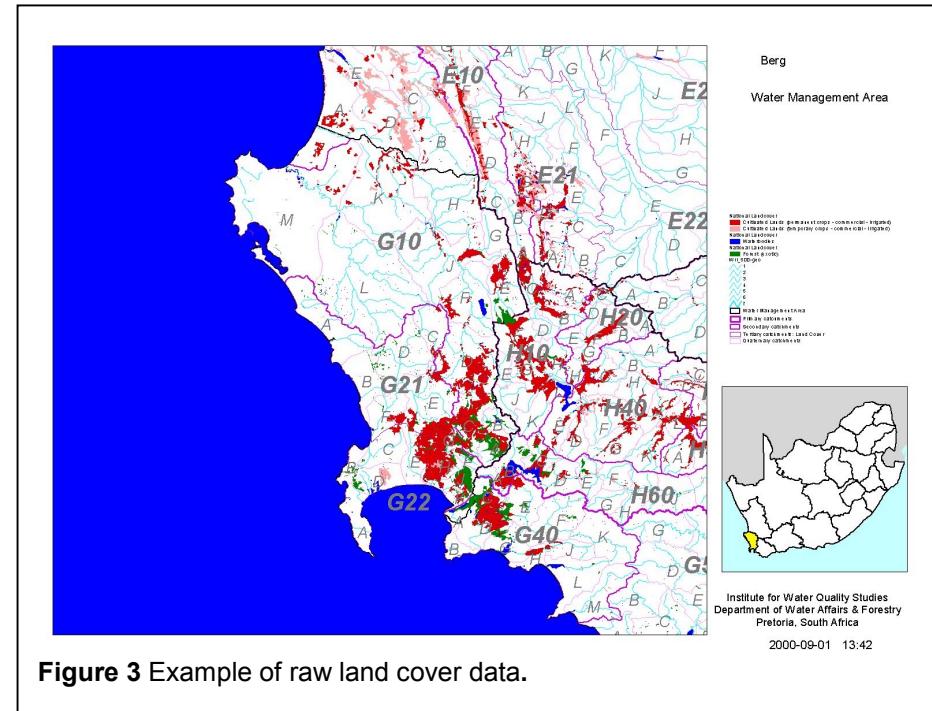

### Web page

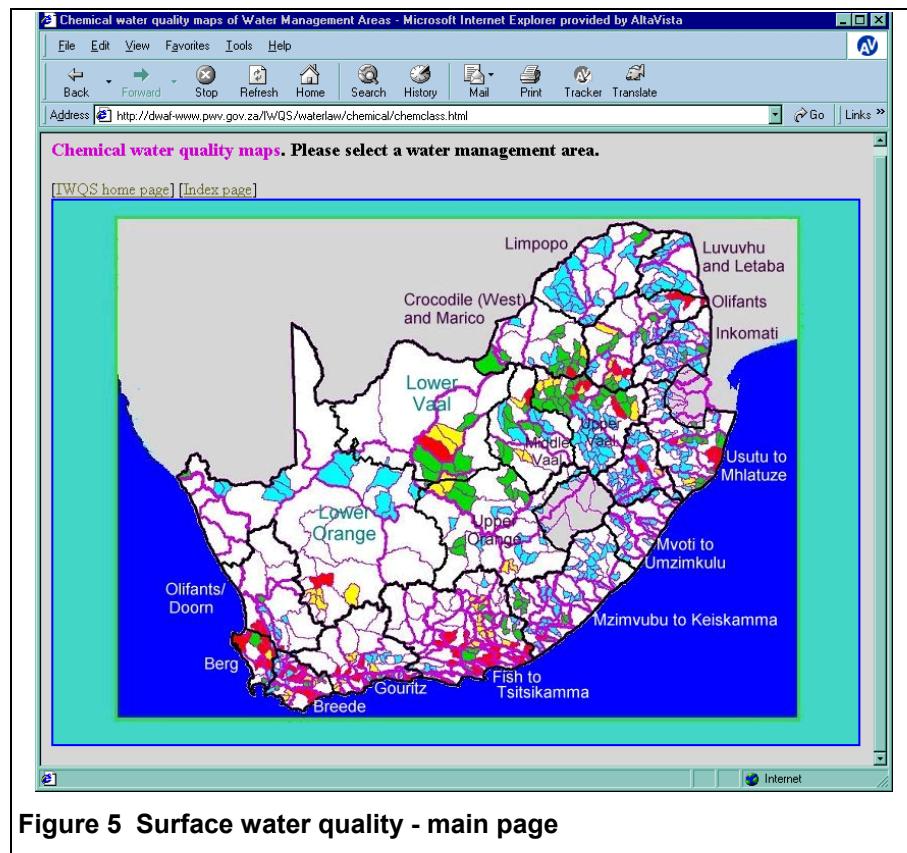

The web pages are located on the Department of Water Affairs and Forestry intranet web site, and are therefore only visible within the government network (Figure 2). A clickable map that allows the user to visually select the water management area of interest is at the head of each set of data.

### Land cover

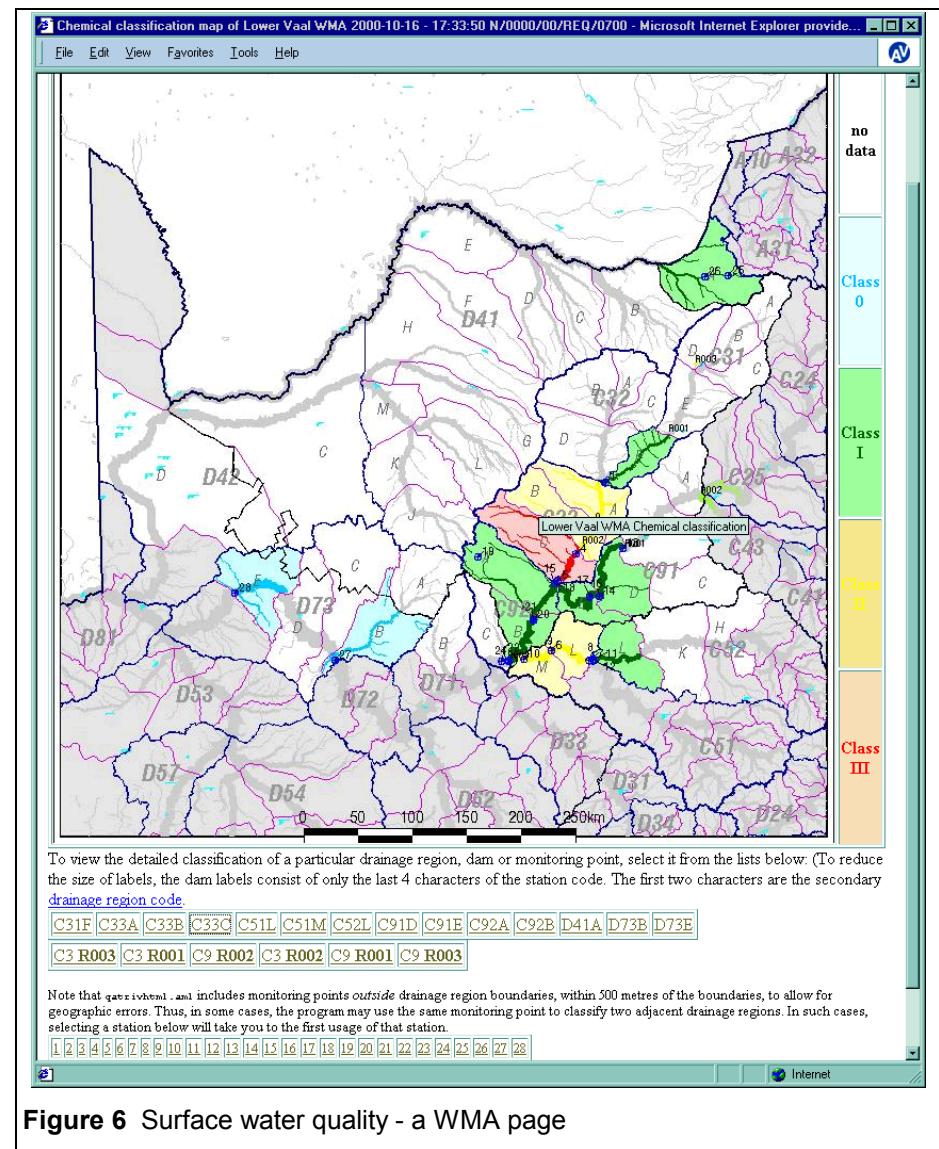

Figure 4 shows the main page for selection of land cover data and Figure 4 shows one of the zoomed-in land cover maps. These are available in "screen" and "print" resolution.

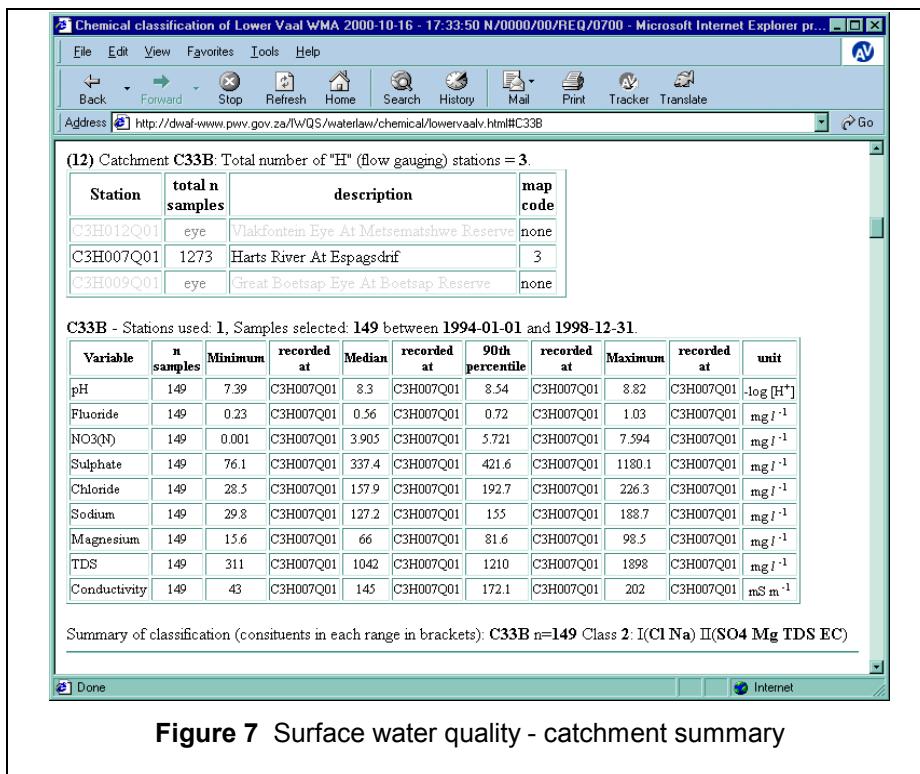

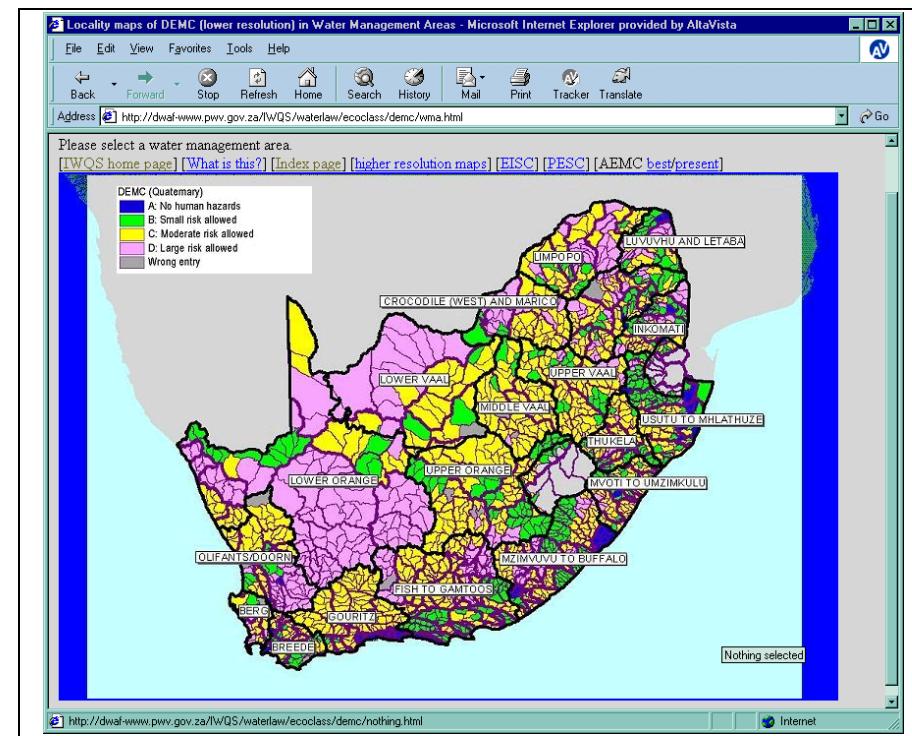

## Surface water quality

A clickable map of South Africa allows the user to select a Water Management Area of interest (Figure 5). The quaternary drainage regions on this map are colour-coded to give an idea of where water quality might be a problem. When the user selects a Water Management Area, a new static HTML page opens, showing a more detailed map and links to information about individual stations (Figure 6).

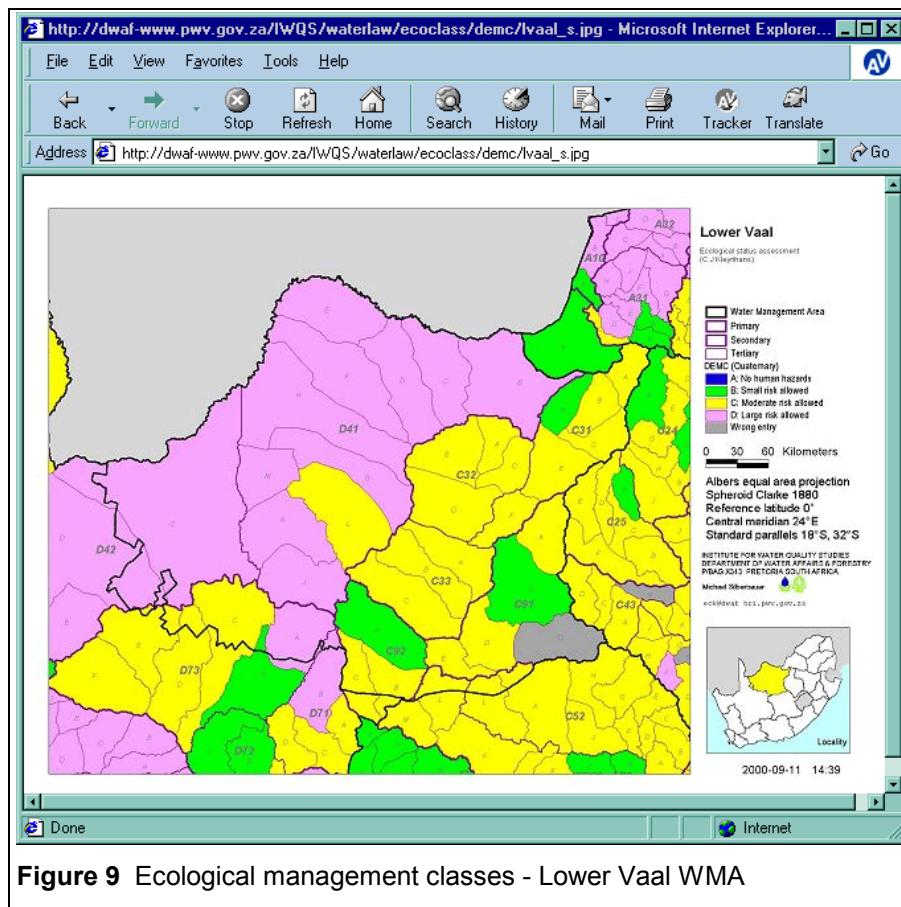

**Figure 7** Surface water quality - catchment summary**Figure 8** Ecological management class - WMA selection screen

The page shows the statistics for or each variable and a summary of the classification process, showing which variables, if any, caused the monitoring point to be in a higher class.

## Ecological classes

Figure 8 shows the navigation screen for selecting a water management area and an ecological classification type. Clicking on one of the water management areas brings up a more detailed map of the water management area showing the classification of each quaternary drainage region (e.g. Figure 9). Higher resolution maps (for printing) are also available.

## Orientation

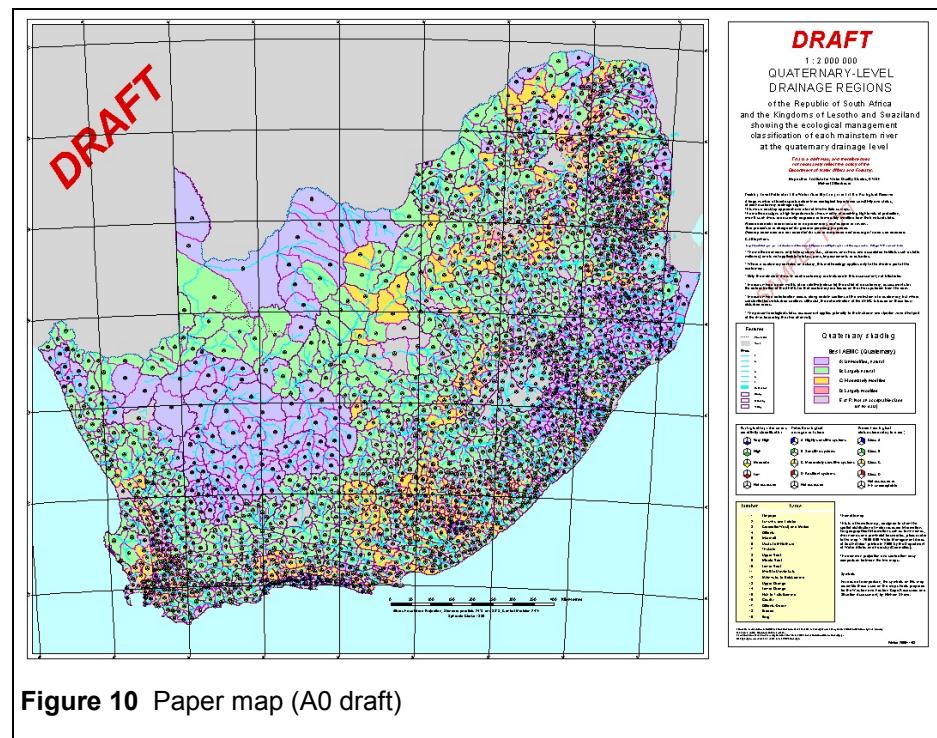

Maps showing only rivers, dams and some place names are available at the "Locality (reference) maps" link in Figure 2.

## Paper maps

Although this project aimed to avoid the printing of large numbers of maps, some users still find paper working maps more convenient than electronic ones, particularly for group discussions or for marking up. Those with their

own large-format printers could download the high-resolution images and print them, while others were reliant on the IWQS for printing.

A proof-of-concept A0-size map (below) included reference text using the layout of the DWAF 2000 Water Management Area map.

## Conclusion

This project has resulted in the development and application of automated techniques for data presentation on the Internet. The scripts in Arc/Info-AML and ArcView-Avenue are now available for general use (see appendices).
