PREAMBLE

In June 2014, two years after the commencement of the uMkhomazi Water Project Phase 1 Feasibility Study, a new Department of Water and Sanitation was formed by Cabinet, including the formerly known Department of Water Affairs.

In order to maintain consistent reporting, all reports emanating from Module 1 of the study will be published under the Department of Water Affairs name.

1 INTRODUCTION

The Smithfield Dam site is located within the Ingwe Local Municipality which falls within the Sisonke District Municipality's area of jurisdiction. Currently there are no communities that will be inundated by the proposed dam. However, several scattered communities, many of which are located on top of hills, surround the Smithfield Dam.

As part of the feasibility study for the proposed Smithfield Dam, a desktop-level study was carried out to ascertain the following:

- The current water sources being used by the communities surrounding the dam; and
- The possibility of feasibly supplying these communities from Smithfield Dam in the future.

For this purpose a desk-top design was carried out for a bulk water supply scheme comprising a (1) water treatment works, (2) pumpstation with associated pump(s), and a (3) pipe network with associated reservoirs. For ease of reference this possible scheme will be referred to as the *Smithfield Dam local water supply scheme (WSS)* for the purpose of this report.

An assumption had to be made on the supply area of the proposed Smithfield Dam local WSS. As such, 24 communities in relatively close proximity of the Smithfield Dam (both on the south-western side and north-eastern side of the dam) were chosen to be included in the scheme. These communities are listed in **Table 3.1** and their locations shown in **Figure 1.1**. It must be noted that this supply area was assumed and should be confirmed by the relevant authorities, should the need arise at a later stage.

No formal communities (apart from Deepdale, Claremont and Camden which only consists of a 4/5 houses each and weren't defined as separate supply areas by the *2001 Census* (Statistics South Africa, 2002)) currently exist within close proximity of the northern side Smithfield Dam. Impendle, which is a considerable distance from the dam falls within the Impendle Town and Enguga WSS, as defined by the *All Towns Reconciliation Strategy* (Water for Africa, Aurecon, Water Geosciences, & Charles Sellick and Associates, 2011).

Figure 1.1: Google image of the communities surrounding Smithfield Dam

2 CURRENT AND ALTERNATIVE FUTURE WATER SOURCES

2.1 CURRENT WATER SOURCES

For the purpose of determining the water sources currently being utilised by the communities surrounding the dam (and assumed to be included in the proposed Smithfield Dam local WSS), information from the *2001 Census* (Statistics South Africa, 2002) was used to be consistent with the information integrated as part of the *water requirements and return flows task* conducted at the beginning of this study. At the time, information from the *2011 Census* wasn't available yet (this only became available on 30 October 2012). The following categories for "access to water" for households were captured during the *2001 Census:*

- Regional/local water scheme (operated by a Water Service Authority or Provider)
 - Piped water (tap) inside dwelling
 - Piped water (tap) inside yard
 - Piped water on community stand: distance less than 200m
 - Piped water on community stand: distance greater than 200m
- Borehole
- Spring
- Rainwater tank (excluded from Figure 2.1 because less than 0.5%)
- Dam/pool/stagnant water
- River/stream
- Water vendor (excluded from Figure 2.1 because less than 0.5%)
- Other

Figure 2.1 provides a summary of the 2013 total water sources being used by the communities surrounding the proposed Smithfield Dam. In addition, the individual charts of each community surrounding the dam are included in **Appendix A**. As can be seen from the combined graph 73% of users currently have access to water services in the form of piped water.

It must be noted that, while capturing information on "access to water" during the 2001 Census many households with piped water did not necessarily know where

the water came from. Enumerators were instructed that, in most cases, piped water came from local or local water schemes, boreholes or springs. They were also told that if the piped water was from a local or local scheme, this should take precedence and that the respondent should not answer, for example, 'borehole', even if the scheme used a borehole. The reason for this approach was that the question was intended to be an indicator of water quality rather than convenience and it was assumed that water from a scheme was of good quality. People who did not have access to water from a scheme were asked to indicate one of the other sources. As such, the exact source of piped water, as indicated by **Figure 2.1**, could not be concluded form the *Census 2001* information.

In addition, according to the *All Towns Reconciliation Strategy* (Water for Africa, Aurecon, Water Geosciences, & Charles Sellick and Associates, 2011) the communities within the Bulwer Donnybrook WSS (defined and discussed in the following **Section 2.2**), which include some of the communities surrounding Smithfield Dam, receive their water from *springs*, *groundwater* and *surface water* supplies from a *weir on the Mkobeni River*.

However, the *All Towns Reconciliation* Strategy didn't make a distinction between the sources of supply to each individual community/supply area, thus this information also didn't assist in a conclusion towards the exact source of piped water to communities surrounding Smithfield Dam.

Figure 2.1: Chart showing total sources of water for communities within the Smithfield Dam local WSS

2.2 ALTERNATIVE FUTURE WATER SOURCES

The proposed supply area of the Smithfield Dam local WSS as defined in Section 1 coincides with the *Bulwer Donnybrook water supply area*. This water supply area was defined by the *All Towns Reconciliation Strategy* (Water for Africa, Aurecon, Water Geosciences, & Charles Sellick and Associates, 2011) and is shown in Figure 2.2 (the Bulwer Donnybrook water supply area is indicated in orange). It is planned as a regional bulk water scheme earmarked to be supplied in future by the proposed Bulwer Dam on the Luhane River (to be augmented from the Pholela River at a later stage).

Other than augmentation from the Bulwer Dam, the Bulwer Donnybrook water supply area could also be augmented in future by (1) groundwater development, and (2) the implementation of a WC/WDM programme.

However, the preferred scheme to supply the Bulwer Donnybrook water supply area in future appears to be the development of storage capacity on the Luhane River (Bulwer Dam to be augmented from the Pholela River at a later stage) together with a regional bulk water scheme from this proposed dam. As such, a detailed feasibility study and detailed design have already been completed for the proposed Bulwer Dam and a water use licence and environmental approval has been obtained (*Gray, Personal Communication, 2014*).

The proposed supply area of the Smithfield Dam local WSS is shown in **Figure 2.3.** This figure also indicates how it coincides with the Bulwer Donnybrook WSS's supply area. The possibility therefore exists to supply the selected communities from the Bulwer Dam, as opposed to implementing a new local WSS.

In order to determine the most feasible scheme to supply the communities around Smithfield Dam it is recommended that the URV of the Smithfield Dam local WSS be compared to that of the Bulwer Donnybrook WSS to be supplied from Bulwer Dam. However, it must be noted that:

- the supply areas of the two schemes differs (with the Bulwer Donnybrook WSS covering a larger area i.e. a greater number of communities will be supplied by this scheme); and
- the proposed Smithfield Dam local WSS is at least ten years away from possible completion due to the anticipated possible implementation dates of the uMWP1. Other localised sources of water will most likely be able to be made available sooner.

Figure 2.2: Water supply areas within the uMkhomazi River catchment as defined by the All Towns Reconciliation Strategy Communities

Figure 2.3: Proposed supply area of the Smithfield Dam local Water Supply Scheme

3 FEASIBILITY OF WATER SUPPLY FROM SMITHFIELD DAM (SMITHFIELD DAM LOCAL WSS)

3.1 DESIGN OF THE SMITHFIELD DAM LOCAL WSS

3.1.1 Description

The supply area of the proposed Smithfield Dam local WSS has been divided into two regions feeding communities to the south and north of the uMkhomazi River. For ease of reference these two regions will be referred to as the *south-western* and *north-eastern* regions respectively.

The proposed Smithfield Dam local WSS has been designed to include the following infrastructure:

- A *pipeline* to abstract water from Smithfield Dam's outlet works;
- A *water treatment works* at the downstream side of the dam wall to treat the raw water from the dam to <u>potable water standards</u>;
- A *pumpstation* at the downstream side of the dam wall with a *pump* requiring 263 kW of power, to circulate the water through the system. With friction losses, the pump connected to the bulk mainlines would be required to pump to a pressure head of 744 m.
- Two bulk mainlines which would deliver water to bulk reservoirs at heights of 1369 masl (south-western line) and 1416 masl (north-eastern line), indicated with yellow markers in Figure 3.1.
- Reserve water storage reservoirs for each community and for each bulk supply line. In this regard two days reserve storage has been allowed for in order to ensure a continued supply to the communities in case of maintenance or malfunction of the system.
- A number of *gravity lines* to deliver water from the bulk reservoirs to the various communities;
- A *booster pump* requiring 50 kW of power for the supply of water to Kwelaba-Ntwana, Enkwelaba Ntwana, Mkobeni Kamensia and Xosheyake from the 1369 masl storage tank (south-western line). This pump would need to supply a further 504 m of pressure head, respectively, when friction losses are taken into consideration.

3.1.2 Water requirements

For the purpose of determining the water requirements of communities within the Smithfield Dam local WSS, population data per sub-place/enumeration area from the 2001 Census (Statistics South Africa, 2002) was used in conjunction with an average per capita consumption of 60 *e/capita/day* (associated with "piped water inside yard" typical for these type of rural areas). This is the preferred allocation for domestic water consumption for households with dry sanitation as given by *Table 9.11: Water consumption in areas equipped with standpipes, yard connections and house connections (adapted from Department of Water Affairs & Forestry, (1992): Guidelines for the selection of design criteria from the Red Book (CSIR Building and Construction Technology, 2000).*

Taking a population growth rate of 1.1% for the Ingwe Local Municipality as taken from *Table 3.9 Annual population growth rates (2001 to 2012)* of report *P WMA 11_U10_00_3312_2_2 - Water Requirements and Return Flows* and applying this growth rate over the lifespan of the pipeline (50 years) to the water demand; these values were used to calculate the water supply design requirements of the system.

The results of these calculations are included in **Table 3.1** and show a total water requirement for the Smithfield Dam local WSS of **0.58 million m³/a** in 2013 and an ultimate water requirement in 2063 of **0.89 million m³/a** based on growth in population over 50 years.

If a future increase in service level is assumed and the average per capita consumption are increased to *90 l/capita/day* in 2063 (which assumes that households will be upgraded to "piped water inside dwelling") the ultimate water requirement in 2063 is estimated to be **1.34 million m³/a**.

The current design, i.e. pipeline network, of the Smithfield Dam local WSS (as discussed in the following section) will be able to accommodate this increased water requirement, however, the pumping requirements will become extensive and will necessitate a re-evaluation of the inclusion of some of the high-lying communities within the scheme.

As this design was only conducted on desktop-level, and the supply area of the Smithfield Dam WSS is still uncertain as discussed in **Section 1**, it is

recommended that an allocation of **1 million m³/a** be made from Smithfield Dam, to be confirmed at a later stage.

This water requirement is deemed sufficient as the current design assumes that the communities within the Smithfield Dam local WSS will *only* be supplied from the dam in future. In actual fact, they may be dually supplied by their current sources i.e. *springs*, *groundwater* and *surface water* supplies from a *weir on the Mkobeni River*, and only augmented from the Smithfield Dam / Bulwer Dam, depending on which scheme are implemented first.

3.1.3 Design

For the determination of the (1) pumps and pumpstation and (2) pipeline planning requirements and costing the *Vaal Augmentation Planning Study - VAPS (DWAF, 1996)* was used as a guide. For this purpose the elevations of the communities, their height above the FSL of the dam (i.e. 930 masl) and the required length of pipeline to supply them with water have been calculated and are summarised in **Table 3.1**. Further to this rates from the *VAPS* were updated to be representative of 2014 costs.

In the case of the (3) water treatment work and the (4) bulk reservoirs and reserve water storage reservoirs unit costs were used to estimate the costs.

3.2 Costs of the Smithfield Dam local WSS

3.2.1 Capital costs

a) Pumps and pumpstations

As mentioned in **Section 3.1** the suggested piping network would require two pumps requiring 288 kW and 50 kW of power respectively, to circulate the water through the system. The capital costs of these, inclusive of civil (30%) and mechanical and electrical (70%) works, were estimated at **R 20.17 million** (excl. VAT). A detailed bill of quantities (BoQ) (based on that obtained from the *Vaal Augmentation Planning Study (DWAF, 1996)*) is included in **Appendix B**).

b) Pipelines

The total capital cost of the pipeline network, including civil works (50%), was found to be approximately **R 47.07 million** (excl. VAT). A detailed BoQ (based on that obtained from the *Vaal Augmentation Planning Study (DWAF, 1996)*) is included in **Appendix C**).

c) Water Treatment Works (WTW)

As stated in Section 3.1 the Smithfield Dam local WSS needs to deliver <u>potable</u> <u>water</u> to communities surrounding the dam. Hence, the costs of treating the raw water to potable water standards needed to be included. As such the capital cost of a WTW located at the dam was determined and is calculated to be approximately **R 8.55 million** (excl. VAT) (based on a unit cost of R3.5 million/Ml/day).

d) Reserve water storage

For each community and for each bulk supply line, 2 days reserve storage has been allowed for as pointed out in **Section 3.1**. The total cost of implementation of the required reservoirs was estimated to be **R 18.96 million** (excl. VAT).

e) Total cost of implementation

Based on the costs as mentioned in Sections 3.2.1 a) to c) the total cost of installing the bulk infrastructure necessary to supply potable water to the

communities surrounding Smithfield Dam has been estimated as **R 94.75 million** (excl. VAT).

Further to this, an additional 10% can be added for engineering fees and 10% for environmental and social costs, bringing the total cost to **R 113.70 million** (excl. VAT).

It is important to note that the initial capital cost of supplying the site with electricity (for the operation of the pumps and WTW) has not been accounted for in this report as the cost of ESKOM infrastructure required for the supply of electricity to the site has been included in the greater *uMkhomazi Water Project Phase 1* project requirements.

3.2.2 Operational and maintenance costs

The estimated amount presented in **Section 3.2.1 e)** only represents the capital costs of implementing the scheme and is therefore not inclusive of any of the following:

- Electricity and associated running costs;
- Maintenance of pumps, pumpstation, pipelines and water treatment works; and
- Employment of professional persons to manage and operate water treatment works and pumpstations and to inspect pipelines.

These costs would be ongoing for the duration of the time that water is treated and pumped to the local communities and are estimated at **R 2.86 million/annum** for operational (electricity) costs and **R 1.60 million/annum** for maintenance costs in 2023, growing to **R 4.43 million/annum** for operational (electricity) costs and **R 1.91 million/annum** for maintenance costs in 2063.

3.3 FEASIBILITY OF THE SMITHFIELD DAM LOCAL WSS

To assess the economic efficiency of the Smithfield Dam local WSS a Unit Reference Value (URV) calculation was conducted. A URV is a common measure in South Africa to assess the economic efficiency of proposed water projects. This found that implementing, operating and maintaining the system from 2023 to 2063 would cost approximately **R 20.84/m³** of water supplied. General assumptions for calculating the URV are included in **Appendix D**.

This URV can now be compared to that of other schemes that are proposed to supply the communities surrounding Smithfield Dam e.g. the Bulwer Donnybrook WSS to be supplied from proposed Bulwer Dam as mentioned in Section 2.2

It must be noted that this URV is very high, and reflects the nature of supplying communities spread out on high lying areas from a large dam low down in a valley. More practical solutions may be sourcing water closer to the communities and at higher elevations. This could for example be the proposed Bulwer Donnybrook WSS for those communities closer to Bulwer, and local ground or surface water for other remote communities.

4 CONCLUSIONS

The following can be concluded with regard to the feasibility of supplying surrounding communities from Smithfield Dam:

Current water resources:

- Based on information from the 2001 Census (Statistics South Africa, 2002)
 73% of users surrounding Smithfield Dam currently have access to some form of piped water.
- However, the exact source of piped water could not be concluded from the Census 2001 information and might be sourced from either springs, groundwater and/or surface water (i.e. a weir on the Mkobeni River).
- In addition, it could also not be concluded whether the water supply of these communities is sufficient and whether the quality of water is acceptable.

Current and future water supply requirements:

- The current combined water requirement of communities within the Smithfield Dam local WSS is in the order of 0.58 million m³/a in 2013 growing to an ultimate future water requirement in 2063 of 0.89 million m³/a. This is based on an average per capita consumption of 60 *e*/*capita/day* (associated with "piped water inside yard" typical for these type of rural areas).
- If an increase in service level is assumed and the average per capita consumption are increased to 90 *l*/capita/day in 2063 (which assumes that households will be upgraded to "piped water inside dwelling") the ultimate water requirement in 2063 is calculated to be 1.34 million m³/a. This is still quite small for a local scheme covering such a large spatial area.

Water supply cost implications:

- The total capital cost of installing the bulk infrastructure necessary to supply potable water to the communities surrounding Smithfield Dam has been estimated as R 113.70 million (including engineering fees and environmental and social costs).
- In addition the operational (electricity) and maintenance costs that would be ongoing for the duration of the time that water is treated and pumped to the local communities is estimated at an ultimate cost of R 4.43 million/annum and R 1.91 million/annum respectively.

- These high costs can mainly be ascribed to the fact that:
 - The communities are spread far apart which would require an extensive piping system in order to provide them with water.
 - The communities have a large elevation difference between them and the FSL of Smithfield Dam (930 masl) resulting in high operation costs

Future water resources:

 Some of the communities surrounding Smithfield Dam are already earmarked to possibly be supplied from the Bulwer Donnybrook WSS. This scheme is currently in planning phase and will be supplied from the proposed Bulwer Dam.

Feasibility of the scheme:

 The URV of the Smithfield Dam-scheme was found to be R 20.84/m³ which is high for a water supply project.

Impact on the uMkhomazi Water Project

The ultimate supply of water to the Smithfield Dam local WSS of 0.89 million m³/a will not have any significant impact on the yield of the dam as it is relatively small (when compared to the transfer of water to the integrated Mgeni WSS that is estimated to be in the order of 336 million m³/a by 2063).

5 RECOMMENDATIONS

The following can be recommended with regard to the feasibility of supplying surrounding communities from Smithfield Dam:

Current water resources:

 An estimated water requirement of approximately 1 million m³/a should be made from Smithfield Dam for the supply of communities surrounding the dam.

Smithfield Dam local WSS vs. Bulwer Donnybrook WSS:

- In order to determine the most feasible scheme to supply the communities around Smithfield Dam it is recommended that the URV of the Smithfield Dam local WSS be compared to that of other schemes proposed for the area i.e. the Bulwer Donnybrook WSS to be supplied from Bulwer Dam.
- However, it must be noted that:
 - the supply areas of the two schemes differs (with the Bulwer Donnybrook WSS covering a larger area i.e. a greater number of communities will be supplied by this scheme);
 - the proposed Smithfield Dam local WSS is at least ten years away from possible completion due to the anticipated possible implementation dates of the uMWP1;
 - Other localised sources of water will therefore most likely be able to be made available sooner i.e. groundwater and management interventions such as Water Conservation/Water Demand Management (WC/WDM).
- Still, a recommendation is made that:
 - the water supply area from the Smithfield Dam (i.e. the Smithfield Dam local WSS) be extended to supply the exact communities earmarked to be supplied from the Bulwer Donnybrook WSS and the URV be recalculated and compared to that of the last-mentioned scheme.
 - the current water available to the communities within the Bulwer Donnybrook WSS be reconciled with the water requirements of these up to 2023 to assess their capacity to await the completion of Smithfield Dam.
 - a water balance and reconciliation study be conducted between the two options to determine the most efficient use of the available water resources.

- In this way:
 - The capital costs of building another stand-alone dam, i.e. Bulwer Dam, can be put off, as the Smithfield Dam will most likely be built to alleviate the current water shortages within the integrated Mgeni WSS, and in this way can be used to fulfil the dual role of supplying local as well as national communities in future.

Detailed feasibility study:

- Based on the above a detailed study should be conducted to analyse and confirm the:
 - Supply area of the Smithfield Dam local WSS/Bulwer Donnybrook WSS.
 - Current water sources utilised by each individual community within the Smithfield Dam local WSS/Bulwer Donnybrook WSS and the portion of the water requirement that could still feasibly be supplied from current, local sources in future (i.e. springs, groundwater and surface water supplies from a weir on the Mkobeni River). It is highly recommended that communities should continue to use their current water sources for as long as possible.
 - Ultimate water requirement of the Smithfield Dam local WSS/Bulwer Donnybrook WSS.
 - The preferred scheme (either the Smithfield Dam local WSS or Bulwer Donnybrook WSS) to supply this area in future.

General:

- It is recommended that the Smithfield Dam local WSS be included as a component in the uMWP1 scheme (and as such the capital cost of the scheme should also be included) with an allocation of 1 million m³/a.
- The possibility of a Smithfield Dam local WSS and treatment plant should be included in the Scoping Report of the EIA.

Appendix D

General assumptions for the URV

calculation of the Smithfield Dam WSS

1. CAPITAL COST

- a) Prices representative of 2013 prices.
- b) 10% for engineering fees and 10% for environmental and social costs is added.
- c) VAT is excluded as the capital gain for governmental purposes is not included in the cost to the economy.

2. OPERATION AND MAINTENANCE

- a) Maintenance costs based on:
 - Civil: 0.25% of the capital cost as an annual maintenance cost
 - Pipelines: 0.5% of the capital cost as an annual maintenance cost
 - Mechanical & Electrical: 4.0% of the capital cost as an annual maintenance cost
- b) Operation costs based on pumping requirements and the marginal cost of coal or nuclear power:
 - Coal: R0.60/kWh for coal fired power with the following transmission fees:
 Natal 10%
 - Nuclear: R1.20/kWh for nuclear power with the following transmission fees:
 - Natal 2%
- c) Coal fired power assumed R0.60/kWh up to 2019, with a blend of coal and nuclear from 2020 onwards at R0.90/kWh. Transmission fees taken as 5% across the country for the coal/nuclear blend.

3. WATER DELIVERY AND PROJECT TIMING

- a) The *Smithfield Dam local WSS* to start delivering water in the same year than the anticipated end of construction of Smithfield Dam in 2023.
- b) Water delivery was grown based on the anticipated growth in population from 2013 to 2063.

4. URV CALCULATIONS

- a) URV calculated for a discount rate of 8% and discounted back to 2013 prices.
- b) URV calculated over a 50 year period (40 years from date of first water delivery).
- c) No allowance made for residual values.

5. PUMPING

0

- a) Pumping 22 hours out of 24 per day (this is 92% of the time which is slightly conservative, but compatible with the DWA standard of 95%).
- b) 33% of the capital cost for pump stations assumed to be civil costs and the remainder (67%) mechanical and electrical costs.

6. TREATMENT COSTS

- a) As the **Smithfield Dam local WSS** needs to deliver potable water to communities the costs of treating the raw water from Smithfield Dam to potable water standards were included in the URV calculation.
- b) An average operating and maintenance costs of treatment of R1/m³ was used.
